Abstract

In developing countries, including Iraq, liver disease virus infection is a severe health issue. The spread of the disease is triggered by various things (things that make it more likely that someone will get an illness that can spread from person to person). In Hilla's area of control/land area (39 cases from 2257 obtained positive results for HBsAg test, most infections in February), the current research was very skillful to devise (a number) of viral liver diseases A and B infections. The study found that infections with the liver disease B virus were more male (51%) than female (49 percent). The highest number of HBVs among people in the 3 age groups (a big change in numbers that means something important) ($p > 0.05$).
